

ABSTRACT OF THE DISCLOSURE

The technique of the invention sets a control start revolution speed N_{start} to decrease with an increase in 5 driver's power demand P^* and with an increase in vehicle speed V (step S130), and motors an engine (steps S150 to S190). When a revolution speed N_e of the engine reaches the setting of the control start revolution speed N_{start} , operation control of the engine starts (step S220). Such 10 settings are ascribed to the following reasons. Setting a relatively small value to the control start revolution speed N_{start} is preferable to trigger an early start of operation control of the engine and ensure quick output of power from the engine. In order to ensure reduction 15 of vibrations of initial explosion and resulting reduction of potential vibrations arising at the time of starting the engine, on the other hand, setting a relatively large value to the control start revolution speed N_{start} is preferable. The driver's sensitivity to the vibrations 20 is lowered with an increase in vehicle speed V .
